# Manycore GPU Architectures and Programming: Outline

---

- Introduction
  - GPU architectures, GPGPUs, and CUDA
- GPU Execution model
- ☞ CUDA Programming model
  - Working with Memory in CUDA
    - Global memory, shared and constant memory
  - Streams and concurrency
  - CUDA instruction intrinsic and library
  - Performance, profiling, debugging, and error handling
  - Directive-based high-level programming model
    - OpenACC and OpenMP

# How is the GPU controlled?

---

- The CUDA API is split into:
  - The CUDA Management API
  - The CUDA Kernel API
- The CUDA Management API is for a variety of operations
  - GPU memory allocation, data transfer, execution, resource creation
  - Mostly regular C function and calls
- The CUDA Kernel API is used to define the computation to be performed by the GPU
  - C extensions

# How is the GPU controlled?

---

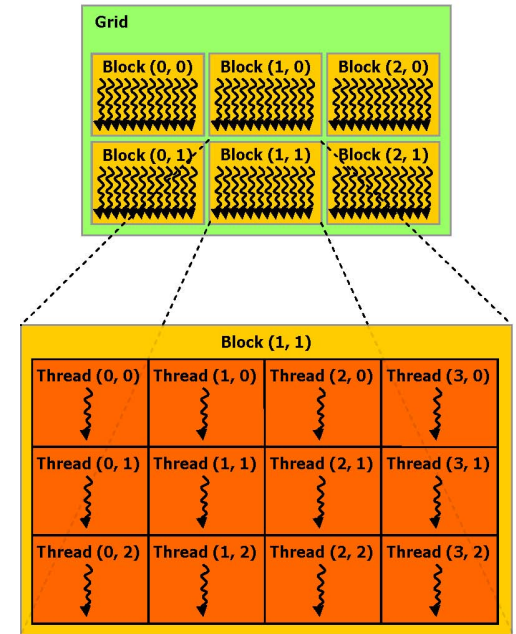

- A CUDA kernel:
  - Defines the operations to be **performed by a single thread** on the GPU
  - Just as a C/C++ function defines work to be done on the CPU
  - Syntactically, a kernel looks like C/C++ with some extensions

```
__global__ void kernel(...) {  
    ...  
}
```

- Every CUDA thread executes the same kernel logic (SIMT)
- Initially, the only difference between threads are their *thread coordinates*

# How are GPU threads organized?

- CUDA thread hierarchy
  - **Warp** = SIMT Group
  - **Thread Block** = SIMT Groups that run concurrently on an SM
  - **Grid** = All Thread Blocks created by the same kernel launch

- Launching a kernel is simple and similar to a function call.
  - kernel name and arguments
  - **# of thread blocks/grid and # of threads/block to create:**

```
kernel<<<nblocks,  
    threads_per_block>>>(arg1, arg2, ...);
```

# How are GPU threads organized?

---

- In CUDA, **only thread blocks and grids are first-class citizens** of the programming model.
- The number of **warps** created and their organization are **implicitly controlled** by the *kernel launch configuration*, but never set explicitly.

```
kernel<<<nblocks,  
threads_per_block>>>(arg1, arg2, ...);
```

kernel launch  
configuration

# How are GPU threads organized?

---

- GPU threads can be configured in one-, two-, or three-dimensional layouts

- One-dimensional blocks and grids:

```
int nblocks = 4;  
int threads_per_block = 8;  
kernel<<<nblocks, threads_per_block>>>(...);
```

# How are GPU threads organized?

---

- GPU threads can be configured in one-, two-, or three-dimensional layouts

- Two-dimensional blocks and grids:

```
dim3 nblocks(2,2)
```

```
dim3 threads_per_block(4,2);
```

```
kernel<<<nblocks, threads_per_block>>>(...);
```

# How are GPU threads organized?

---

- GPU threads can be configured in one-, two-, or three-dimensional layouts

– Two-dimensional grid and one-dimensional blocks:

```
dim3 nblocks(2,2);  
int threads_per_block = 8;  
kernel<<<nblocks, threads_per_block>>>(...);
```

# How are GPU threads organized?

- On the GPU, the number of blocks and threads per block is exposed through intrinsic thread coordinate variables:
  - **Dimensions**
  - **IDs**

Variable	Meaning
<code>gridDim.x, gridDim.y, gridDim.z</code>	Number of blocks in a kernel launch.
<code>blockIdx.x, blockIdx.y, blockIdx.z</code>	Unique ID of the block that contains the current thread.
<code>blockDim.x, blockDim.y, blockDim.z</code>	Number of threads in each block.
<code>threadIdx.x, threadIdx.y, threadIdx.z</code>	Unique ID of the current thread within its block.

# How are GPU threads organized?

to calculate a **globally unique ID** for a thread on the GPU inside a one-dimensional grid and one-dimensional block:

```
kernel<<<4, 8>>>(...);
```

```
__global__ void kernel(...) {
```

```
    int tid = blockIdx.x * blockDim.x + threadIdx.x;
```

```
    ...
```

```
}
```

blockIdx.x = 2;

blockDim.x = 8;

threadIdx.x = 2;

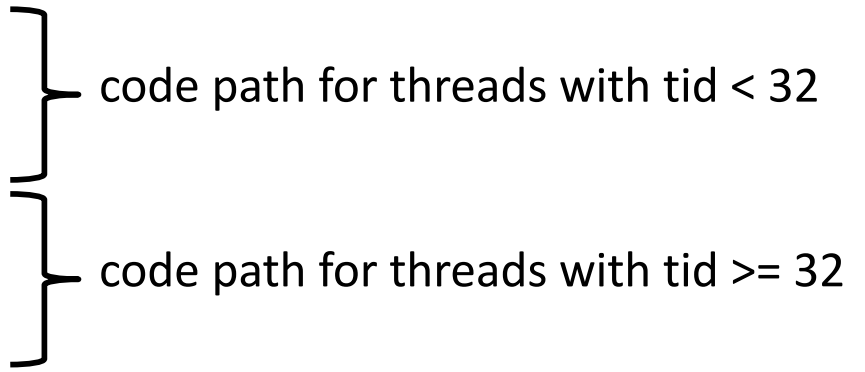

# How are GPU threads organized?

---

- Thread coordinates offer a way to differentiate threads and identify thread-specific input data or code paths.
  - Link data and computation, a mapping

```
__global__ void kernel(int *arr) {  
    int tid = blockIdx.x * blockDim.x + threadIdx.x;  
    if (tid < 32) {  
        arr[tid] = f(arr[tid]);  
    } else {  
        arr[tid] = g(arr[tid]);  
    }  
}
```

The diagram shows two code paths for threads with tid < 32 and tid >= 32. The first path is for threads with tid < 32, and the second path is for threads with tid >= 32. The code is color-coded: green for the global keyword, black for the function signature and variable declarations, red for the if condition and function call, blue for the else block and function call, and black for the closing braces.

Thread Divergence: recall that useless code path is executed, but then disabled in SIMT execution model

# How is GPU memory managed?

---

- CUDA Memory Management API
  - Allocation of GPU memory
  - Transfer of data from the host to GPU memory
  - Free-ing GPU memory
  - `Foo(int A[][N]) { }`

Host Function	CUDA Analogue
<code>malloc</code>	<code>cudaMalloc</code>
<code>memcpy</code>	<code>cudaMemcpy</code>
<code>free</code>	<code>cudaFree</code>

# How is GPU memory managed?

---

```
cudaError_t cudaMalloc(void **devPtr,  
                        size_t size);
```

- Allocate `size` bytes of GPU memory and store their address at `*devPtr`

```
cudaError_t cudaFree(void *devPtr);
```

- Release the device memory allocation stored at `devPtr`
- Must be an allocation that was created using `cudaMalloc`

# How is GPU memory managed?

---

```
cudaError_t cudaMemcpy(  
    void *dst, const void *src, size_t count,  
    enum cudaMemcpyKind kind);
```

- Transfers count bytes from the memory pointed to by src to dst
- kind can be:
  - **cudaMemcpyHostToHost,**
  - **cudaMemcpyHostToDevice,**
  - **cudaMemcpyDeviceToHost,**
  - **cudaMemcpyDeviceToDevice**
- The locations of dst and src must match kind, e.g. if kind is cudaMemcpyHostToDevice then src must be a host array and dst must be a device array

# How is GPU memory managed?

---

```
void *d_arr, *h_arr;
h_addr = ... ; /* init host memory and data */
// Allocate memory on GPU and its address is in d_arr
cudaMalloc((void **)&d_arr, nbytes);

// Transfer data from host to device
cudaMemcpy(d_arr, h_arr, nbytes,
           cudaMemcpyHostToDevice);

// Transfer data from a device to a host
cudaMemcpy(h_arr, d_arr, nbytes,
           cudaMemcpyDeviceToHost);

// Free the allocated memory
cudaFree(d_arr);
```

# CUDA Program Flow

---

- At its most basic, the flow of a CUDA program is as follows:
  1. Allocate GPU memory
  2. Populate GPU memory with inputs from the host
  3. Execute a GPU kernel on those inputs
  4. Transfer outputs from the GPU back to the host
  5. Free GPU memory
- Let's take a look at a simple example that manipulates data

# AXPY Example with OpenMP: Multicore

- $y = \alpha \cdot x + y$ 
  - $x$  and  $y$  are vectors of size  $n$
  - $\alpha$  is scalar

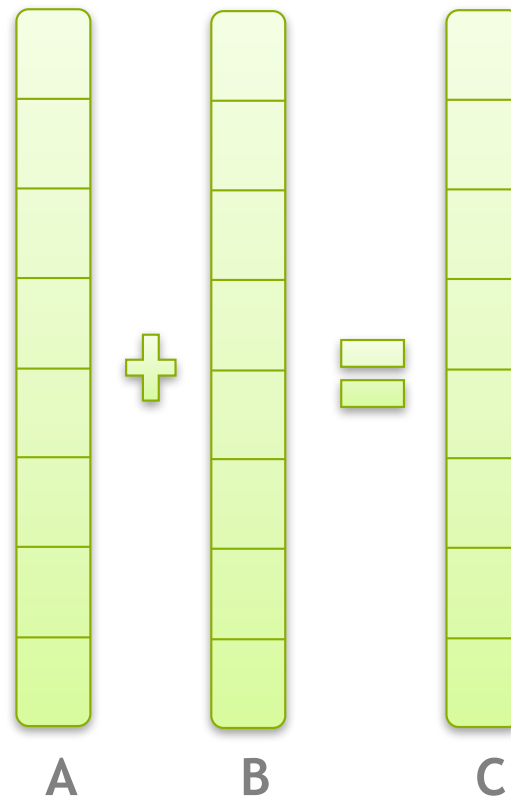

```
1 void axpy(REAL *x, REAL *y, long n, REAL a) {  
2     #pragma omp parallel for shared(x, y, n, a)  
3     for (int i = 0; i < n; ++i)  
4         y[i] += a * x[i];  
5 }
```

- Data ( $x$ ,  $y$  and  $a$ ) are shared
  - Parallelization is relatively easy

# CUDA Program Flow

---

- AXPY is an **embarrassingly parallel problem**
  - How can vector addition be parallelized?
  - How can we map this to GPUs?
- Each thread does one element

# AXPY Offloading To a GPU using CUDA

```
1 // CUDA kernel. Each thread takes care of one element of c
2 __global__ void axpy(REAL *x, REAL *y, int n, REAL a) {
3     int id = blockIdx.x*blockDim.x+threadIdx.x;
4     if (id < n) y[id] += a * x[id];
5 }
6
7 int main( int argc, char* argv[] ) {
8
9     // ... init host a, x and y
10    // Allocate memory for each vector on GPU
11    cudaMalloc(&d_x, size);
12    cudaMalloc(&d_y, size);
13
14    // Copy host vectors to device
15    cudaMemcpy( d_x, h_x, size, cudaMemcpyHostToDevice);
16    cudaMemcpy( d_y, h_y, size, cudaMemcpyHostToDevice);
17
18    int blockSize, gridSize;
19    blockSize = 1024;
20    gridSize = (int)ceil((float)n/blockSize);
21    axpy<<<gridSize, blockSize>>>(d_x, d_y, n, a);
22
23    // Copy array back to host
24    cudaMemcpy( h_y, d_y, size, cudaMemcpyDeviceToHost );
25
26    // Release device memory
27    cudaFree(d_x);
28    cudaFree(d_y);
29 }
```

Memory allocation on device

Memcpy from host to device

Launch parallel execution

Memcpy from device to host

Deallocation of dev memory

# CUDA Program Flow

- Consider the workflow of the example vector addition `vecAdd.cu`:
  1. Allocate space for  $A$ ,  $B$ , and  $C$  on the GPU
  2. Transfer the initial contents of  $A$  and  $B$  to the GPU
  3. Execute a kernel in which each thread sums  $A_i$  and  $B_i$ , and stores the result in  $C_i$
  4. Transfer the final contents of  $C$  back to the host
  5. Free  $A$ ,  $B$ , and  $C$  on the GPU

**Modify to  $C = A+B+C$**

**$A = B*C;$**

**we will need both  $C$  and  $A$  in the host side after GPU computation.**

- Compile and running on bridges:
  - <https://passlab.github.io/CSCE569/resources/HardwareSoftware.html#interactive>
  - copy `gpu_code_examples` folder from my home folder
    - `cp -r ~/yan/gpu_code_examples ~`
  - `$nvcc -Xcompiler -fopenmp vectorAdd.cu`
  - `./a.out`

# More Examples and Exercises

---

- Matvec:
  - Version 1: each thread computes one element of the final vector
  - Version 2:
- Matmul in assignment #4
  - Version 1: each thread computes one row of the final matrix C

# CUDA SDK Examples

---

- CUDA Programming Manual:
  - <http://docs.nvidia.com/cuda/cuda-c-programming-guide>
- CUDA SDK Examples on bridges
  - `module load gcc/5.3.0 cuda/8.0`
  - `export CUDA_PATH=/opt/packages/cuda/8.0`
  - `/opt/packages/cuda/8.0/samples`
- Copy to your home folder
  - `cp -r /opt/packages/cuda/8.0/samples ~/CUDA_samples`
- Do a “make” in the folder, and it will build all the sources
- Or go to a specific example folder and make, it will build only the binary
- Find ones you are interested in and run to see

# Inspecting CUDA Programs

---

- Debugging CUDA program:
  - `cuda-gdb` debugging tool, like `gdb`
- Profiling a program to examine the performance
  - `Nvprof` tool, like `gprof`
  - `Nvprof ./vecAdd`

# Storing Data on the CPU

---

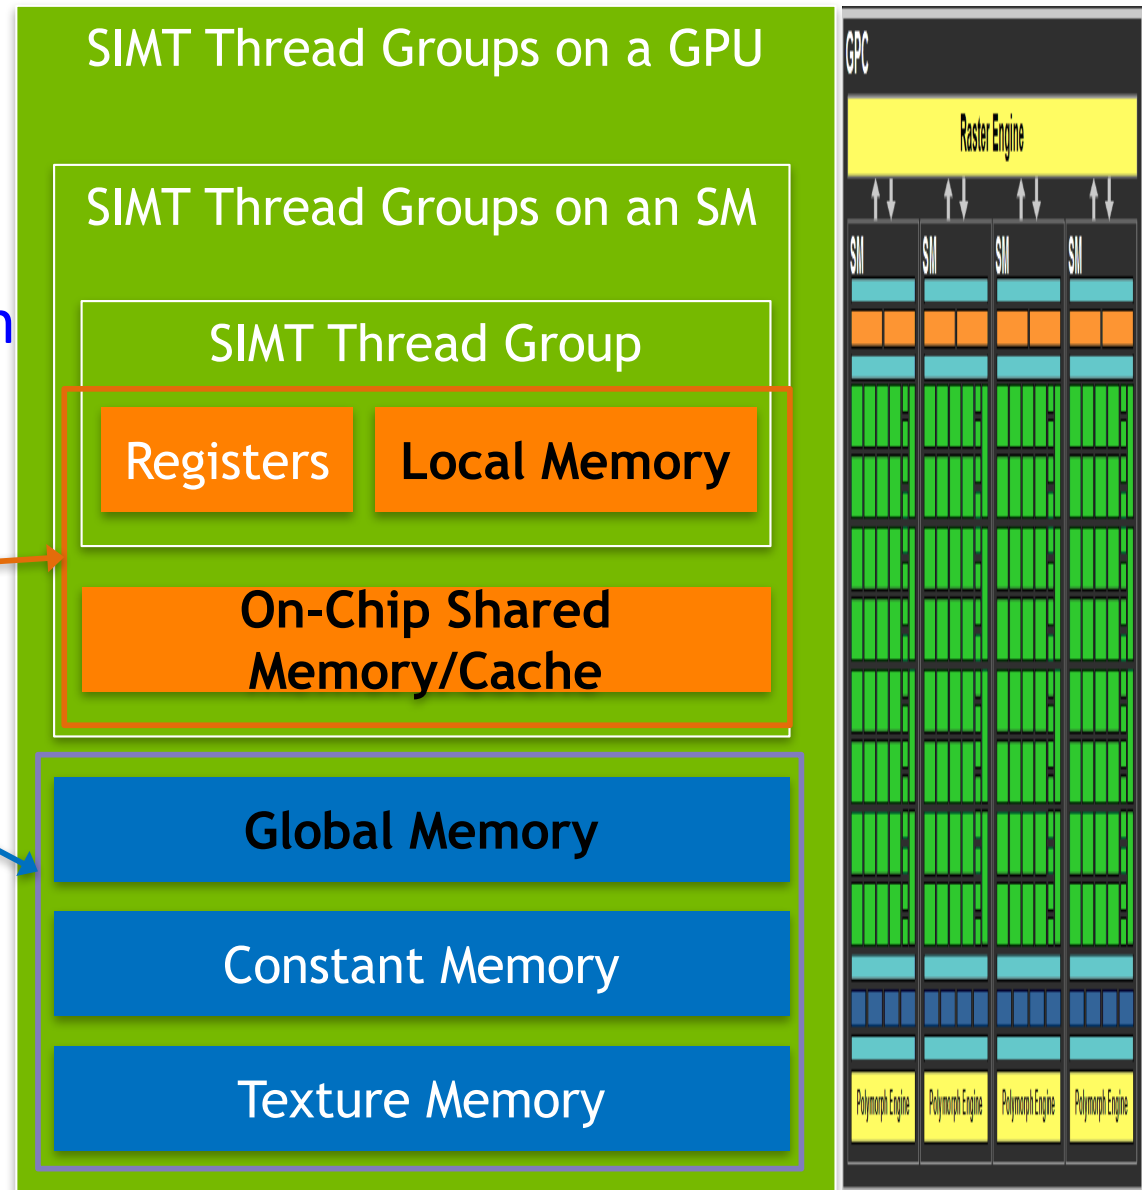

- A memory hierarchy emulates a large amount of low-latency memory
  - Cache data from a large, high-latency memory bank in a small low-latency memory bank

CPU Memory Hierarchy

# GPU Memory Hierarchy

- More complex than the CPU memory
  - **Many different** types of memory, each with special-purpose characteristics
    - **SRAM**
    - **DRAM**
  - More **explicit** control over data movement

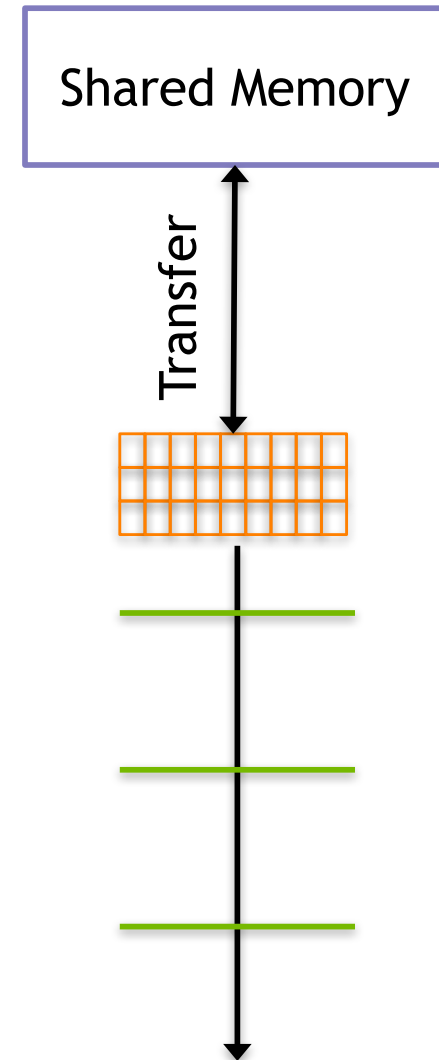

# Storing Data on the GPU

- Registers (SRAM)
  - Lowest latency memory space on the GPU
  - **Private to each CUDA thread**
  - Constant pool of registers per-SM divided among threads in resident thread blocks
  - Architecture-dependent limit on number of registers per thread
  - Registers are not explicitly used by the programmer, implicitly allocated by the compiler
  - `-maxrregcount` compiler option allows you to limit # registers per thread

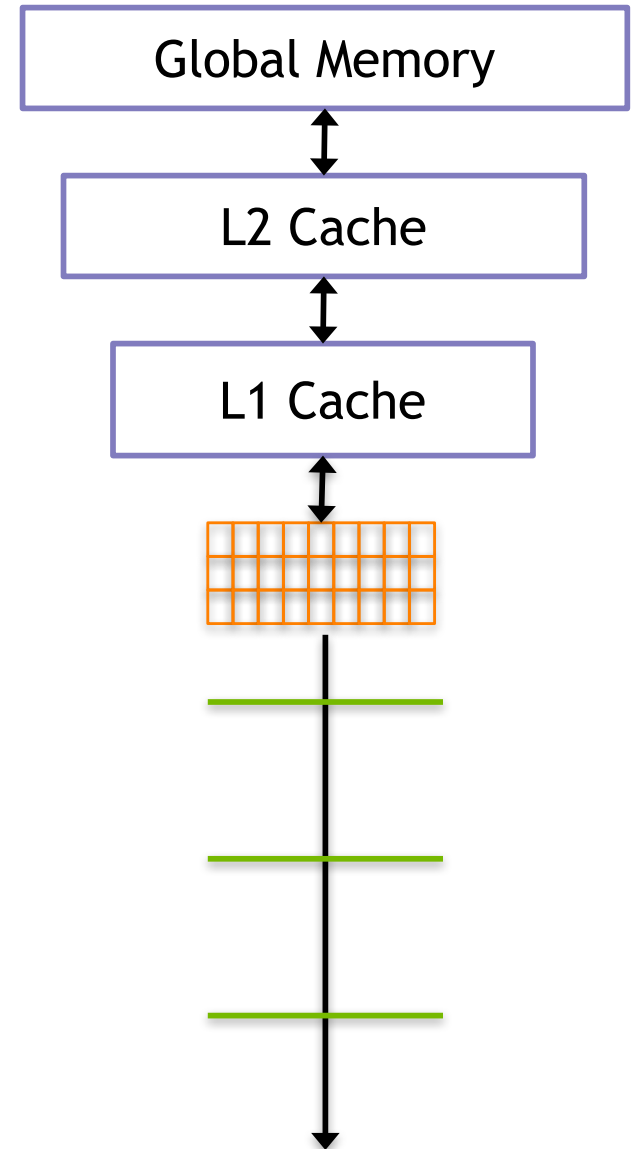

# Storing Data on the GPU

- **Shared Memory (SRAM)**
  - Declared with the `__shared__` keyword
  - Low-latency, high bandwidth
  - **Shared by all threads in a thread block**
  - Explicitly allocated and managed by the programmer, manual L1 cache
  - Stored on-SM, same physical memory as the GPU L1 cache
  - **On-SM memory is statically partitioned between L1 cache and shared memory**

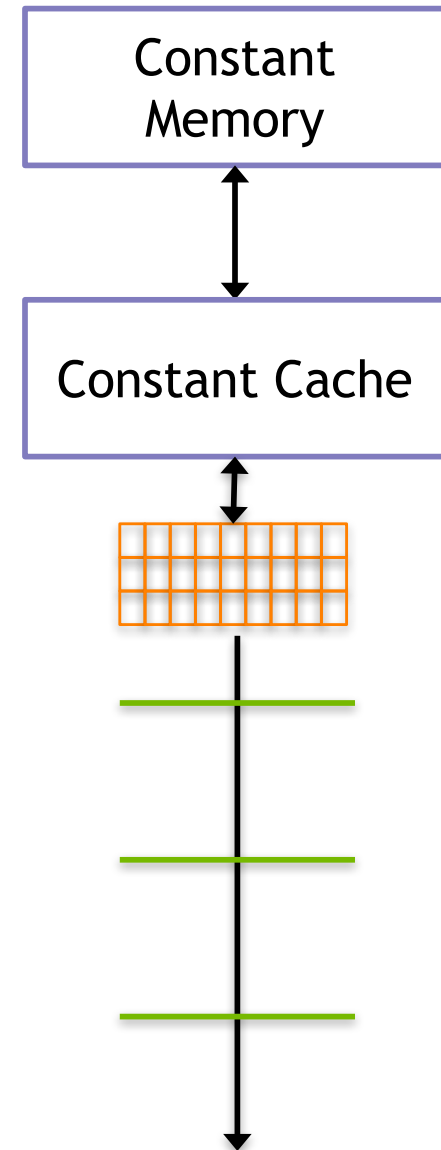

# Storing Data on the GPU

- GPU Caches (SRAM)
  - Behaviour of GPU caches is architecture-dependent
  - **Per-SM L1 cache stored on-chip**
  - **Per-GPU L2 cache stored off-chip, caches values for all SMs**
  - Due to parallelism of accesses, GPU caches do not follow the same LRU rules as CPU caches

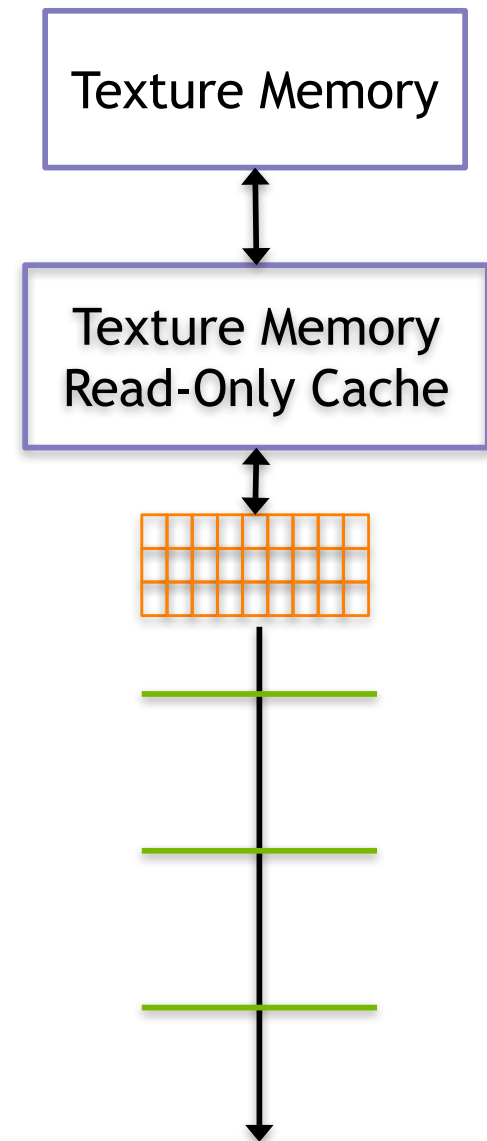

# Storing Data on the GPU

- Constant Memory (DRAM)
  - Declared with the `__constant__` keyword
  - Read-only
  - Limited in size: 64KB
  - Stored in device memory (same physical location as Global Memory)
  - Cached in a per-SM constant cache
  - Optimized for all threads in a warp accessing the same memory cell

# Storing Data on the GPU

- Texture Memory (DRAM)
  - **Read-only**
  - **Stored in device memory (same physical location as Global Memory)**
  - Cached in a texture-only on-SM cache
  - Optimized for 2D spatial locality (caches commonly only optimized for 1D locality)
  - Explicitly used by the programmer
  - Special-purpose memory

# Storing Data on the GPU

- **Global Memory (DRAM)**
  - Large, high-latency memory
  - Stored in device memory (along with constant and texture memory)
  - Can be declared statically with `__device__`
  - Can be allocated dynamically with `cudaMalloc`
  - Explicitly managed by the programmer
  - Optimized for all threads in a warp accessing neighbouring memory cells

# Storing Data on the GPU

MEMORY	ON/OFF CHIP	CACHED	ACCESS	SCOPE	LIFETIME
Register	On	n/a	R/W	1 thread	Thread
Local	Off	†	R/W	1 thread	Thread
Shared	On	n/a	R/W	All threads in block	Block
Global	Off	†	R/W	All threads + host	Host allocation
Constant	Off	Yes	R	All threads + host	Host allocation
Texture	Off	Yes	R	All threads + host	Host allocation

# Storing Data on the GPU

QUALIFIER	VARIABLE NAME	MEMORY	SCOPE	LIFESPAN
	float var	Register	Thread	Thread
	float var[100]	Local	Thread	Thread
<code>__shared__</code>	float var †	Shared	Block	Block
<code>__device__</code>	float var †	Global	Global	Application
<code>__constant__</code>	float var †	Constant	Global	Application

# Static Global Memory

---

- Static Global Memory has a fixed size throughout execution time:

```
__device__ float devData;  
__global__ void checkGlobalVariable()  
    printf("devData has value %f\n", devData);  
}
```

- Initialized using `cudaMemcpyToSymbol`:

```
cudaMemcpyToSymbol(devData, &hostData, sizeof(float));
```

- Fetched using `cudaMemcpyFromSymbol`:

```
cudaMemcpyFromSymbol(&hostData, devData,  
sizeof(float));
```

# Dynamic Global Memory

---

- We have already seen dynamic global memory
  - `cudaMalloc` dynamically allocates global memory
  - `cudaMemcpy` transfers to/from global memory
  - `cudaFree` frees global memory allocated by `cudaMalloc`
- `cudaMemcpy` supports 4 types of transfer:
  - `cudaMemcpyHostToHost`,  
`cudaMemcpyHostToDevice`,  
`cudaMemcpyDeviceToHost`,  
`cudaMemcpyDeviceToDevice`
- You can also `memset` global memory

```
cudaError_t cudaMemcpy(void *devPtr, int value,  
size_t count);
```

# Global Memory Access Patterns

---

- CPU caches are optimized for linear, iterative memory accesses
  - Cache lines ensure that accessing one memory cell brings neighbouring memory cells into cache
  - If an application exhibits good spatial or temporal locality (which many do), later references will also hit in cache

# Global Memory Access Patterns

---

- GPU caching is a more challenging problem
  - Thousands of threads cooperating on a problem
  - Difficult to predict the next round of accesses for all threads
- For efficient global memory access, GPUs instead rely on:
  - Large device memory bandwidth
  - Aligned and coalesced memory access patterns
  - Maintaining sufficient pending I/O operations to keep the memory bus saturated and hide global memory latency

# Global Memory Access Patterns

---

- Achieving **aligned** and **coalesced** global memory accesses is key to optimizing an application's use of global memory bandwidth
  - Coalesced: the threads within a warp reference memory addresses that can all be serviced by a single global memory transaction (think of a memory transaction as the process of bring a cache line into the cache)
  - Aligned: the global memory accesses by threads within a warp start at an address boundary that is an even multiple of the size of a global memory transaction

# Global Memory Access Patterns

---

- A global memory transaction is either 32 or 128 bytes
  - The size of a memory transaction depends on which caches it passes through
  - If L1 + L2: 128 byte
  - If L2 only: 32 bytes
  - Which caches a global memory transaction passes through depends on GPU architecture and the type of access (read vs. write)

# Global Memory Access Patterns

- Aligned and Coalesced Memory Access (*w/ L1 cache*)
  - 32-thread warp, 128-bytes memory transaction

- With 128-byte access, a single transaction is required and all of the loaded bytes are used

# Global Memory Access Patterns

- Misaligned and Coalesced Memory Access (*w/ L1 cache*)

- With 128-byte access, two memory transactions are required to load all requested bytes. Only half of the loaded bytes are used.

# Global Memory Access Patterns

- Misaligned and Uncoalesced Memory Access (w/ L1 cache)

- With uncoalesced loads, many more bytes loaded than requested

# Global Memory Access Patterns

- Misaligned and Uncoalesced Memory Access (*w/ L1 cache*)

- One factor to consider with uncoalesced loads: while the efficiency of this access is very low it may bring many cache lines into L1/L2 cache which are used by later memory accesses. The GPU is flexible enough to perform well, even for applications that present suboptimal access patterns.

# Global Memory Access Patterns

---

- Memory accesses that are not cached in L1 cache are serviced by 32-byte transactions
  - This can improve memory bandwidth utilization
  - However, the L2 cache is device-wide, higher latency than L1, and still relatively small → many applications may take a performance hit if L1 cache is not used for reads

# Global Memory Access Patterns

- Aligned and Coalesced Memory Access (*w/o L1 cache*)

- With 32-byte transactions, four transactions are required and all of the loaded bytes are used

# Global Memory Access Patterns

---

- Misaligned and Coalesced Memory Access (*w/o L1 cache*)

- With 32-byte transactions, extra memory transactions are still required to load all requested bytes but the number of wasted bytes is likely reduced, compared to 128-byte transactions.

# Global Memory Access Patterns

- Misaligned and Uncoalesced Memory Access (w/o L1 cache)

- With uncoalesced loads, more bytes loaded than requested but better efficiency than with 128-byte transactions

# Global Memory Access Patterns

- Global Memory Writes are always serviced by 32-byte transactions

# Global Memory and Special-Purpose Memory

---

- Global memory is widely useful and as easy to use as CPU DRAM
- Limitations
  - Easy to find applications with memory access patterns that are intrinsically poor for global memory
  - Many threads accessing the same memory cell → poor global memory efficiency
  - Many threads accessing sparse memory cells → poor global memory efficiency
- Special-purpose memory spaces to address these deficiencies in global memory
  - Specialized for different types of data, different access patterns
  - Give more control over data movement and data placement than CPU architectures do

# Shared Memory

- Declared with the `__shared__` keyword
- **Low-latency, high bandwidth**
- **Shared by all threads in a thread block**
- Explicitly allocated and managed by the programmer, manual L1 cache
- Stored on-SM, same physical memory as the GPU L1 cache
- On-SM memory is statically partitioned between L1 cache and shared memory

# Shared Memory Allocation

---

- Shared memory can be allocated statically or dynamically
- Statically Allocated Shared Memory
  - Size is fixed at compile-time
  - Can declare many statically allocated shared memory variables
  - Can be declared globally or inside a device function
  - Can be multi-dimensional arrays

```
shared int s_arr[256][256];
```

# Shared Memory Allocation

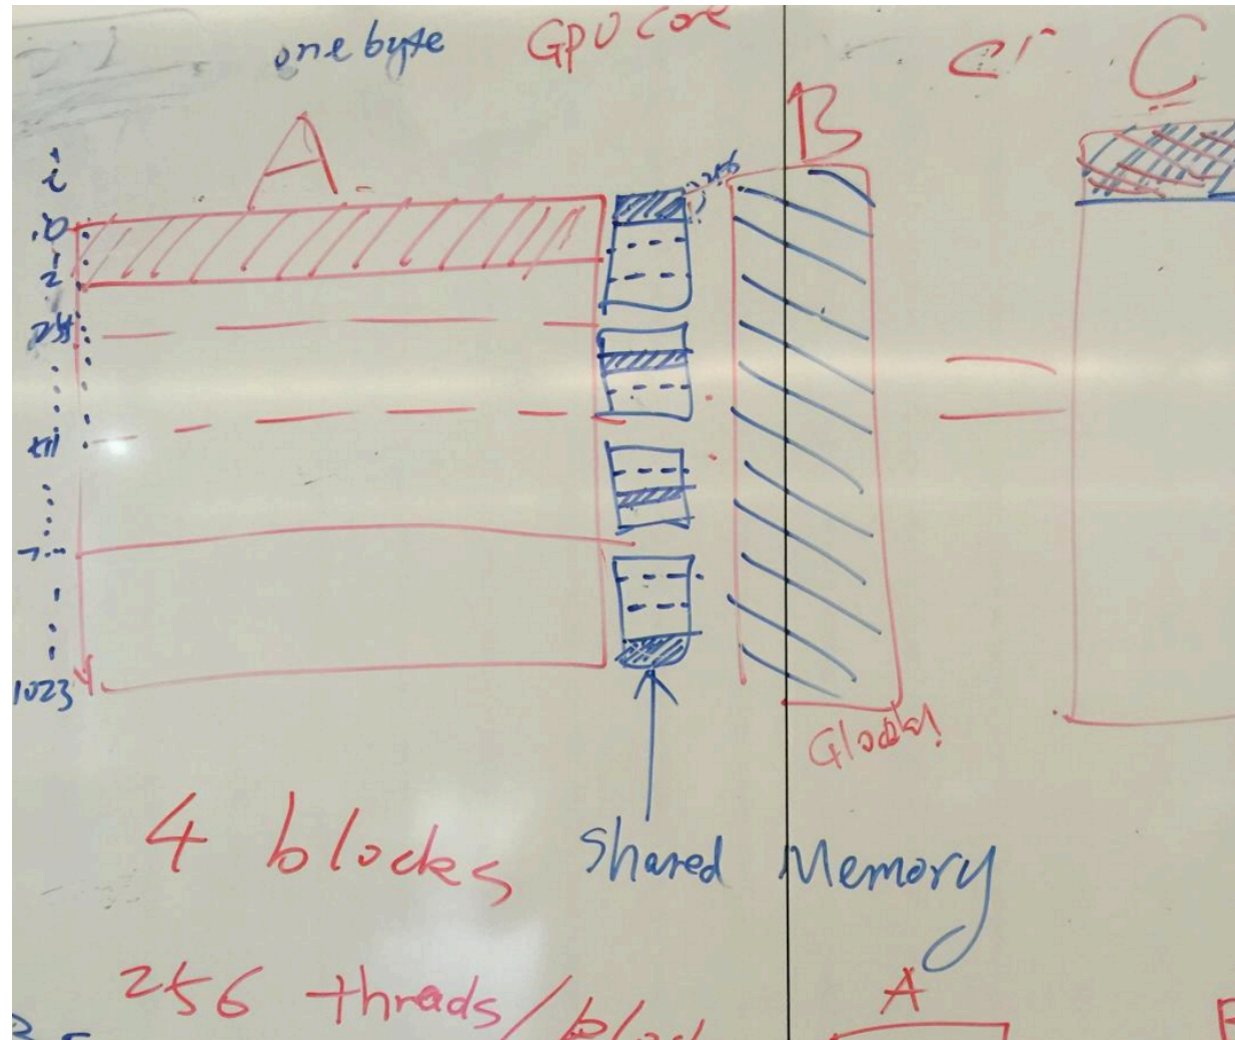

---

- Dynamically Allocated Shared Memory
  - Size in bytes is set at kernel launch with a third kernel launch configurable
  - Can only have one dynamically allocated shared memory array per kernel
  - Must be one-dimensional arrays

```
__global__ void kernel(...) {  
    extern __shared__ int s_arr[];  
    ...  
}
```

```
kernel<<<nblocks, threads_per_block,  
shared_memory_bytes>>>(...);
```

# Matvec using shared memory

# Matrix Vector Multiplication

```
58 /** N =1024, 4 blocks, 256 threads/per block */
59 __global__ void
60 matvec_kernel_shared(float * A, float * B, float * C, int N) {
61     int i = blockDim.x * blockIdx.x + threadIdx.x; /* 0 - 1023 */
62     int j;
63
64     extern __shared__ float B_shared[]; /* the same size as B[1024] */
65     B_shared[i] = B[i];
66     /* for block 0: 0-255 are filled */
67     /* for block 1: 256-511 are filled */
68     /* for block 2: 512-767 are filled */
69     /* for block 3: 768 - 1023 are filled */
70
71     B_shared[(i+256)%1024] = B[(i+256)%1024];
72     B_shared[(i+512)%1024] = B[(i+512)%1024];
73     B_shared[(i+768)%1024] = B[(i+768)%1024];
74
75     __syncthreads();
76
77     if (i < N) {
78         float temp = 0.0;
79         for (j=0; j<N; j++)
80             temp += A[i*N+j] * B_shared[j];
81
82         C[i] = temp;
83     }
84 }
```

# Matrix Vector Multiplication

---

```
86 __global__ void
87 matvec_kernel_shared_general(float * A, float * B, float * C, int N) {
88     int i = blockDim.x * blockIdx.x + threadIdx.x; /* 0 - 1023 */
89     int j;
90
91     extern __shared__ float B_shared[];
92     int k;
93     for (k=0; k<gridDim.x; k++) {
94         B_shared[(threadIdx.x + k*blockDim.x)%N] = B[(threadIdx.x + k*blockDim.x)%N];
95     }
96
97     __syncthreads();
98
99     if (i < N) {
100         float temp = 0.0;
101         for (j=0; j<N; j++)
102             temp += A[i*N+j] * B_shared[j];
103
104         C[i] = temp;
105     }
106 }
```

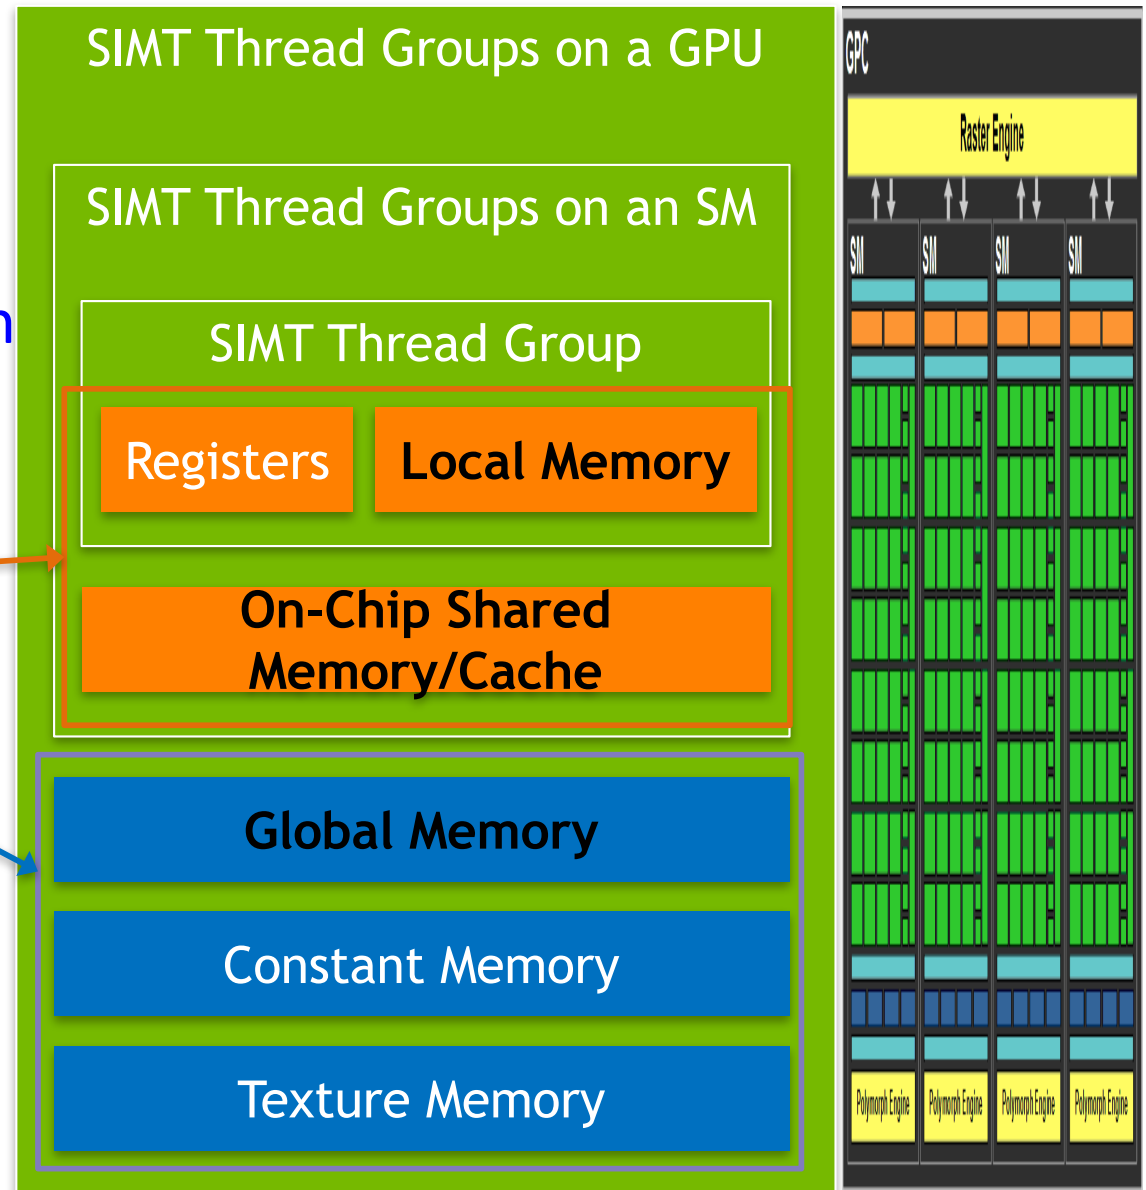

# Matrix Multiplication V1 and V2 in Assignment #4

- <https://docs.nvidia.com/cuda/cuda-c-programming-guide/#shared-memory>

# GPU Memory Hierarchy

- More complex than the CPU memory
  - **Many different** types of memory, each with special-purpose characteristics
    - **SRAM**
    - **DRAM**
  - More **explicit** control over data movement

# Constant Memory

- Declared with the `__constant__` keyword
- Read-only
- Limited in size: 64KB
- Stored in device memory (same physical location as Global Memory)
- Cached in a per-SM constant cache
- Optimized for all threads in a warp accessing the same memory cell

# Constant Memory

---

- As its name suggests, constant memory is best used for storing constants
  - Values which are read-only
  - Values that are accessed identically by all threads
- For example: suppose all threads are evaluating the equation

$$y = mx + b$$

for different values of  $x$ , but identical values of  $m$  and  $b$

- All threads would reference  $m$  and  $b$  with the same memory operation
- This broadcast access pattern is optimal for constant memory

# Constant Memory

---

- A simple 1D stencil
  - target cell is updated based on its 8 neighbors, weighted by some constants  $c_0, c_1, c_2, c_3$

$$f'(x) \approx c_0 (f(x + 4h) - f(x - 4h)) + c_1 (f(x + 3h) - f(x - 3h)) \\ - c_2 (f(x + 2h) - f(x - 2h)) + c_3 (f(x + h) - f(x - h))$$

# Constant Memory

---

- `constantStencil.cu` contains an example 1D stencil that uses constant memory

```
__constant__ float coef[RADIUS + 1];
```

```
cudaMemcpyToSymbol(coef, h_coef, (RADIUS + 1) *  
sizeof(float));
```

```
__global__ void stencil_1d(float *in, float *out, int N)  
{  
    ...  
    for (int i = 1; i <= RADIUS; i++) {  
        tmp += coef[i] * (smem[side + i] - smem[side - i]);  
    }  
}
```

# CUDA Synchronization

---

- When using shared memory, you often must coordinate accesses by multiple threads to the same data
- CUDA offers synchronization primitives that allow you to synchronize among threads

# CUDA Synchronization

---

## **\_\_syncthreads**

- Synchronizes execution across all threads in a thread block
- No thread in a thread block can progress past a `__syncthreads` before all other threads have reached it
- `__syncthreads` ensures that all changes to shared and global memory by threads in this block are visible to all other threads in this block

## **\_\_threadfence\_block**

- All writes to shared and global memory by the calling thread are visible to all other threads in its block after this fence
- Does not block thread execution

# CUDA Synchronization

---

## \_\_threadfence

- All writes to global memory by the calling thread are visible to all other threads in its grid after this fence
- Does not block thread execution

## \_\_threadfence\_system

- All writes to global memory, page-locked host memory, and memory of other CUDA devices by the calling thread are visible to all other threads on all CUDA devices and all host threads after this fence
- Does not block thread execution
